AWS Solutions Architect role, the interview will likely test your **architecture thinking**, **hands-on experience**, **cost optimization**, **security best practices**, and ability to design **scalable and resilient systems**.

Here's a list of **essential AWS interview Q&A** with **examples**, tailored for a senior-level Solution Architect role.

---

1. Q: How do you design a highly available and fault-tolerant architecture in AWS?

A:

- Use **Multi-AZ** and **Multi-Region** deployments.
- **Auto Scaling Groups** for EC2 instances.
- Use **Elastic Load Balancers (ALB/NLB)** across multiple Availability Zones.
- Store data in **S3** or **RDS with Multi-AZ** or **Aurora Global Database**.
- Use **Route 53** for DNS-based routing and health checks.

Example:

For a global web application, we used ALB in front of EC2 Auto Scaling groups in two AZs. The DB layer was Aurora Global DB for cross-region replication, and S3 for static content. Route 53 did latency-based routing across regions for resilience.

---

2. Q: How would you design a secure and scalable API using AWS services?

A:

- Use **Amazon API Gateway** to expose REST/HTTP APIs.
- **Lambda** for backend logic (serverless).
- Use **Cognito** for user authentication or **IAM roles** for service access.
- Apply **rate limiting** and **throttling** at API Gateway.
- Enable **WAF** and **CloudFront** for additional security and caching.

Example:

For a mobile backend, designed an API using API Gateway + Lambda + DynamoDB. We used Cognito for user pools, encrypted all data at rest and in transit, and integrated with CloudWatch for monitoring.

---

3. Q: What is the difference between scalability and elasticity in AWS?

A:

- **Scalability**: Ability to increase resources to meet demand (vertical or horizontal scaling).
- **Elasticity**: Ability to automatically provision and de-provision resources based on demand.

Example:

An EC2 Auto Scaling Group with a target tracking policy scales based on CPU utilization — that's elasticity. Migrating to a microservices architecture to independently scale services — that's scalability.

---

4. Q: How would you secure an application running on EC2?

A:

- Use **Security Groups** to restrict inbound/outbound traffic.
- Use **NACLs** for subnet-level control.
- Keep EC2 instances in **private subnets**, use **bastion host** or **Session Manager**.
- Enable **IAM roles** for permissions (never use hardcoded credentials).
- Patch OS regularly and use **SSM Patch Manager**.
- Enable **CloudTrail**, **VPC Flow Logs**, and **GuardDuty**.

Example:

We used EC2 in private subnets with no public IPs, accessed via SSM. Security groups allowed only ALB traffic. IAM roles restricted access to S3. CloudTrail and GuardDuty were used for continuous monitoring.

---

5. Q: How do you reduce AWS costs in an enterprise architecture?

A:

- **Right-size** instances using **Cost Explorer** and **Compute Optimizer**.
- Use **Savings Plans** or **Reserved Instances** for predictable workloads.
- Use **S3 Intelligent-Tiering** or lifecycle policies for storage.
- Leverage **Lambda** or **Fargate** for short-lived compute.
- Monitor using **CloudWatch**, set up **budgets and alerts**.

Example:

helped reduce monthly spend by 30% by converting On-Demand EC2 to Savings Plans, moving batch jobs to Lambda, and applying S3 lifecycle rules to move old logs to Glacier Deep Archive.

---

6. Q: How would you design a hybrid cloud architecture using AWS?

A:

- Use **AWS Direct Connect** or **Site-to-Site VPN** for on-prem to AWS connectivity.
- Extend on-prem AD with **AWS Directory Service**.
- Use **Storage Gateway** for hybrid file storage.
- Place shared components (e.g., databases) in **private subnets**, expose services through **VPC endpoints** or **Transit Gateway**.

Scenario:

A banking client needed to move workloads gradually to AWS. We established Direct Connect for low-latency, high-bandwidth connection, deployed Storage Gateway for backup, and used Transit Gateway to connect multiple VPCs and their on-prem data center.

---

7. Q: Explain how you would implement centralized logging in AWS.

A:

- Use **CloudWatch Logs** for collecting logs.
- Forward logs from Lambda/EC2/ECS to a **central CloudWatch log group**.
- Use **Kinesis Firehose** to stream logs to **S3**, **Elasticsearch (OpenSearch)**, or **third-party tools** like Splunk.
- Optionally use **AWS Organizations** with a **central logging account**.

Scenario:

For an enterprise with multiple accounts, created a central logging account using AWS Organization SCPs and forwarded all VPC Flow Logs, CloudTrail, and CloudWatch logs via Kinesis Firehose to S3 for long-term analysis and compliance.

---

8. Q: What is an AWS Transit Gateway and when would you use it?

A:

- **Transit Gateway** connects multiple VPCs and on-prem networks via a hub-and-spoke model.
- Simplifies routing compared to VPC peering.
- Supports **centralized network management** and **inter-region peering**.

Scenario:

A retail client had 10+ VPCs for different departments. We replaced a complex mesh of VPC peerings with a single Transit Gateway, drastically reducing route table management and improving network visibility.

---

9. Q: How would you implement multi-account architecture in AWS?

A:

- Use **AWS Organizations** to group and manage accounts.
- Apply **Service Control Policies (SCPs)** for permission boundaries.
- Use **AWS Control Tower** or **Landing Zone** to automate setup.
- Isolate environments (prod, dev, staging) into separate accounts.
- Centralize logging, billing, and security using **delegated admin accounts**.

Scenario:

In a Fortune 500 migration, we implemented AWS Control Tower with account vending for each business unit, used SCPs to enforce tagging policies, and centralized GuardDuty, Security Hub, and CloudTrail logs in dedicated accounts.

---

10. Q: How would you handle disaster recovery (DR) in AWS?

A:

- Choose DR strategy: **Backup & Restore**, **Pilot Light**, **Warm Standby**, or **Multi-site Active-Active**.
- Use **S3 Cross-Region Replication**, **RDS Multi-AZ/Read Replica**, and **Route 53 failover routing**.
- Automate infrastructure with **CloudFormation** or **Terraform**.
- Regularly test DR using **AWS Fault Injection Simulator**.

Scenario:

For a healthcare app, we used a warm standby setup in a secondary region with AMIs and RDS replicas. Route 53 failed over traffic automatically when the primary region went down during testing.

---

11. Q: How do you enforce security best practices in AWS?

A:

- Enable **CloudTrail**, **Config**, **GuardDuty**, **Inspector**, and **Security Hub**.
- Enforce **IAM least privilege** access, MFA, and **role-based access control**.
- Encrypt everything using **KMS**.
- Use **SCPs** and **IAM permission boundaries**.
- Automate audits with **AWS Config Rules** and **Config Conformance Packs**.

Scenario:

We built a compliance dashboard using AWS Config and Security Hub across all accounts. If an S3 bucket was made public, a Lambda function auto-remediated it and notified the security team via SNS.

---

12. Q: How would you handle secret management in AWS?

A:

- Use **AWS Secrets Manager** or **Parameter Store (SSM)**.
- Enable **automatic rotation** for DB credentials and API keys.
- Use **IAM roles** for access instead of embedding secrets.
- Integrate with **Lambda**, **ECS**, **EC2**, or **EKS** securely.

Scenario:

In a microservices architecture, we used Secrets Manager to store RDS and third-party API credentials. We rotated them every 30 days automatically and attached fine-grained IAM policies to each service.

---

13. Q: How do you implement CI/CD using AWS services?

A:

- Use **CodeCommit**, **CodeBuild**, **CodeDeploy**, and **CodePipeline**.
- Or integrate with external tools like GitHub and GitLab.
- Use **CodeDeploy Blue/Green** for EC2/ECS deployments.
- Trigger pipelines via **webhooks** or **CloudWatch Events**.

Scenario:

We built a pipeline using GitHub → CodeBuild → CodeDeploy for a containerized app on ECS Fargate. CodeDeploy used blue/green deployments with Lambda hooks for pre/post-deployment validation.

---

14. Q: How do you implement auto-scaling in AWS?

A:

- Use **Auto Scaling Groups** for EC2 with target tracking (e.g., 60% CPU).
- Use **ECS/Fargate** Service Auto Scaling (based on CPU/memory or queue length).
- Use **Lambda** with concurrency limits.
- Use **DynamoDB Auto Scaling** for table throughput.

Scenario:

A video processing app scaled from 10 to 200 EC2 instances during peak hours. We used step scaling policies with CloudWatch alarms and attached a lifecycle hook to notify Slack on scale-out events.

---

15. Q: How do you optimize AWS networking for performance and cost?

A:

- Use **VPC endpoints** for private access to AWS services.
- Use **Global Accelerator** for low-latency routing.
- Use **CloudFront** for caching static/dynamic content.
- Compress and batch data to minimize transfer.
- Place compute and data in same AZ or region to reduce inter-AZ costs.

Scenario:

We optimized a data analytics workload by moving S3 access from public internet to VPC endpoints, saving ~$2,000/month. We also used CloudFront and gzip compression for frontend assets.

---

16. Q: How do you secure access to S3 buckets in a multi-account setup?

A:

- Use **bucket policies** with **Principal** field to allow access from specific IAM roles/accounts.
- Enable **S3 Block Public Access** at account and bucket level.
- Use **VPC endpoint policies** to restrict access from private networks.
- Enable **S3 server-side encryption (SSE-KMS)**.
- Use **Access Analyzer** to audit permissions.

Scenario:

A SaaS platform shared S3 buckets with partners across accounts. We enforced access via resource-based policies, disabled public access, and restricted traffic through VPC endpoints using condition keys like aws:SourceVpc.

---

17. Q: How would you manage and monitor cost in a large AWS environment?

A:

- Enable **AWS Cost Explorer**, **Budgets**, and **Billing alerts**.
- Use **resource tags** for cost allocation.
- Apply **Savings Plans**, **RI recommendations**, and **Compute Optimizer** insights.
- Build dashboards using **Athena + S3 + QuickSight** on CUR (Cost & Usage Report).

Scenario:

For a FinTech client, we built a cost dashboard pulling CUR into Athena, joined with resource tags (e.g., env, project) and visualized in QuickSight. This identified underutilized RIs and idle EBS volumes.

---

18. Q: How do you design a scalable architecture for an event-driven system?

A:

- Use **Amazon SNS** for pub/sub messaging or **EventBridge** for event routing.
- Use **SQS** as a buffer for processing.
- Backend processing with **Lambda**, **ECS**, or **Kinesis Consumers**.
- Ensure **DLQs** (Dead Letter Queues) are enabled for failure scenarios.

Scenario:

In an IoT platform, devices sent telemetry data to SNS → SQS. Lambda functions processed SQS messages and pushed data to DynamoDB. Failed messages went to DLQ for analysis and retry logic.

---

19. Q: What is the difference between AWS Cognito and IAM? When would you use each?

A:

- **IAM** is for **AWS resource access control** (for users, roles, services).
- **Cognito** is for **user identity and federation**, used in applications (web/mobile).
- Use Cognito to authenticate end users via social login, SAML, or user pools.

Scenario:

For a mobile app, Cognito handled user authentication with Google/Facebook sign-in. It issued temporary IAM credentials via identity pools for accessing S3, ensuring secure and short-lived access tokens.

---

20. Q: How would you architect a global content delivery solution?

A:

- Use **Amazon CloudFront** as a CDN.
- Host static content in **S3**.
- Enable **geo-restriction** and **signed URLs** for secure access.
- Use **Lambda@Edge** for request/response manipulation.
- Use **Route 53 latency-based routing** or **Global Accelerator**.

Scenario:

A video streaming client used CloudFront with multiple origins (S3 for static, ALB for dynamic). We added signed URLs for premium content and Lambda@Edge for header manipulation based on viewer location.

---

21. Q: How would you implement a data lake on AWS?

A:

- Store raw data in **S3 (data lake)**.
- Use **Glue Crawlers** to catalog metadata into **Glue Data Catalog**.
- Query with **Athena**, process with **Glue ETL** or **EMR**.
- Use **Lake Formation** for fine-grained access control.
- Apply lifecycle rules for storage tiering.

Scenario:

For a retail analytics project, we built a data lake in S3 with daily ingestion via Firehose. Glue crawlers updated schema, Athena queried raw logs, and Lake Formation provided data access controls for analysts.

---

22. Q: How do you implement blue/green or canary deployments in AWS?

A:

- Use **CodeDeploy** for EC2/ECS with blue/green deployments.
- Use **Lambda aliases and weights** for canary traffic shifting.
- Implement health checks and rollback logic.
- Use **feature flags** with tools like **LaunchDarkly** or custom config.

Scenario:

For a Java app on ECS, we used CodeDeploy blue/green strategy. New versions launched on a parallel task set, traffic shifted via ALB gradually. Lambda pre/post hooks checked for performance issues before shifting 100% traffic.

---

23. Q: How do you ensure compliance (e.g., HIPAA, PCI) in AWS?

A:

- Use **AWS Artifact** for audit reports.
- Enable **CloudTrail**, **Config**, **GuardDuty**, and **Security Hub**.
- Encrypt data at rest (KMS) and in transit (TLS).
- Isolate workloads in **dedicated VPCs** and enforce **NACLs** and **SGs**.
- Use **Macie** for sensitive data discovery.

Scenario:

A healthcare app followed HIPAA by enabling encryption, logging, audit trail, and using Macie to scan S3 for PHI. Config conformance packs enforced resource compliance across environments.

---

24. Q: What is the difference between ALB and NLB? When would you choose one over the other?

A:

- **ALB (Application Load Balancer)**: Layer 7, supports host/path routing, WebSocket, SSL termination.
- **NLB (Network Load Balancer)**: Layer 4, extremely low latency, supports static IP and TLS passthrough.

Scenario:

We used ALB for a web app requiring routing based on /api vs /static, and WebSocket support. For a high-throughput financial app, we used NLB due to its performance and TCP support for FIX protocol.

---

25. Q: How would you migrate an on-premise application to AWS with minimal downtime?

A:

- Use **Server Migration Service (SMS)** or **Application Migration Service (MGN)**.

- Set up **replication**, perform **cutover during low-traffic window**.
- Use **DNS switch** via Route 53 post-migration.
- Validate with staging/test environment before production switchover.

Scenario:

For a legacy .NET app, we used AWS MGN to replicate VMs to EC2. After testing the target environment and ensuring data consistency, we switched DNS via Route 53 and decommissioned the on-prem servers.

---

26. Q: How do you manage infrastructure as code (IaC) in AWS?

A:

- Use **AWS CloudFormation** or **Terraform** for IaC.
- Separate templates/modules for networking, compute, storage, etc.
- Use **SSM Parameters**, **Mappings**, and **Conditionals** in CloudFormation.
- Store templates in **version-controlled repos** and integrate with CI/CD.

Scenario:

We used Terraform with GitLab CI to provision VPCs, RDS, and ECS clusters. Each environment (dev/stage/prod) had its own workspace, and modules were reused across teams.

---

27. Q: How would you ensure RDS is secure and performant in production?

A:

- Place RDS in **private subnets**.
- Enable **encryption at rest** (KMS) and **in transit** (SSL).
- Use **IAM authentication** instead of username/password.
- Enable **automatic backups**, **multi-AZ**, and **performance insights**.

Scenario:

For a payments app, we used Aurora with encryption, fine-grained IAM access, CloudWatch alarms on slow queries, and enabled multi-AZ for high availability.

---

28. Q: How do you monitor and alert for AWS workloads?

A:

- Use **CloudWatch Metrics**, **Alarms**, and **Logs**.
- Aggregate logs using **CloudWatch Logs Insights** or **ELK/OpenSearch**.
- Use **CloudWatch Synthetics** for canaries (URL health).
- Send alerts via **SNS**, integrate with **PagerDuty**, **Slack**, or **Opsgenie**.

Scenario:

We set up canary tests every 5 minutes on the login page. Errors triggered CloudWatch Alarms → SNS → PagerDuty, giving early warnings before users reported issues.

---

29. Q: How do you manage cross-region data replication?

A:

- Use **S3 Cross-Region Replication** (CRR) for object storage.
- **RDS Global Databases** (Aurora) for low-latency global reads.
- Use **DynamoDB Global Tables** for active-active data.
- Use **CloudFront** or **Global Accelerator** for performance boost.

Scenario:

For a global e-commerce app, we replicated DynamoDB tables across NA and APAC using Global Tables. S3 used CRR for media assets, and RDS had read replicas in the secondary region.

---

30. Q: How do you protect APIs hosted on AWS from attacks?

A:

- Use **API Gateway** with **WAF** and **rate limiting**.
- Enable **authorization via Cognito** or **Lambda authorizers**.
- Use **Shield Advanced** for DDoS protection.
- Log requests using **CloudWatch** and **X-Ray**.

Scenario:

For a public REST API, we used API Gateway throttling (100 RPS), WAF rules for SQLi/XSS, and Cognito-based auth. Shield Advanced helped mitigate DDoS attempts during a bot attack.

---

31. Q: How do you manage Kubernetes (EKS) in AWS securely?

A:

- Use **IAM roles for service accounts (IRSA)** to grant pod-level access.
- Restrict **kubectl access** via **RBAC** and **IAM-authenticator**.
- Enable **encryption with KMS** for secrets.
- Use **security groups per pod** and **network policies**.

Scenario:

We migrated a legacy cluster to EKS, used IRSA for pod credentials (no secrets in config), enforced RBAC for dev teams, and applied Calico for fine-grained network isolation.

---

32. Q: What's your approach to tagging and resource organization in AWS?

A:

- Use consistent **tagging policies** (e.g., Environment, Owner, CostCenter, Project).
- Enforce tags using **SCPs**, **Config Rules**, or **Tag Policies**.
- Use **resource groups** and **Cost Explorer** for analysis.
- Automate tagging in IaC templates.

Scenario:

We implemented mandatory tags via Config Rules and rejected resource creation without Environment and Owner tags. Monthly reports were filtered using tag-based cost breakdown.

---

33. Q: How would you manage application secrets and credentials securely?

A:

- Use **Secrets Manager** or **SSM Parameter Store** with KMS encryption.
- Avoid hardcoding credentials; use IAM roles for applications.
- Enable **rotation policies** and integrate with database secrets.

Scenario:

In a Lambda-based service, we stored DB credentials in Secrets Manager, rotated them every 7 days, and used environment variables populated at runtime via Boto3.

---

34. Q: How do you handle versioning and rollback for Lambda functions?

A:

- Use **Lambda versions** and **aliases**.
- Point alias (e.g., "prod") to a stable version.
- Implement **canary or linear deployment** strategies with CodeDeploy.
- Rollback automatically on failure.

Scenario:

We used CodeDeploy to roll out a new Lambda in 10% increments. When an error rate spike was detected via CloudWatch Alarms, CodeDeploy rolled back to the previous version automatically.

---

35. Q: How do you implement caching in AWS for performance?

A:

- Use **CloudFront** to cache static and dynamic content.
- Use **Elasticache (Redis/Memcached)** for application-layer caching.
- Use **API Gateway caching** for backend responses.
- Apply **S3 TTL** for object-level expiration.

Scenario:

For a news site, we cached category pages in CloudFront and used Redis for real-time trending articles. API Gateway cached common queries, reducing Lambda invocations by 50%.

---

36. Q: How do you secure a public-facing web application in AWS?

A:

- Use **CloudFront** with **WAF** for edge protection.
- Deploy app behind **ALB** with **SSL/TLS termination**.
- Place EC2/ECS behind ALB in **private subnets**.
- Use **Security Groups**, **IAM roles**, and **GuardDuty**.
- Enable **Shield Advanced** for DDoS protection.

Scenario:

For a fintech app, we placed CloudFront with WAF in front of ALB + ECS. Only ALB accepted HTTPS, with strict security headers and rate-limiting rules. GuardDuty alerted us on suspicious access patterns.

---

37. Q: What is AWS Control Tower and when would you use it?

A:

- **AWS Control Tower** sets up and governs a secure, multi-account AWS environment using **Landing Zone**.
- Pre-configures **Organizational Units**, **guardrails (SCPs)**, **CloudTrail**, **Config**, and **account vending**.

Scenario:

A client with 20+ accounts wanted governance. We deployed Control Tower, enforcing security guardrails, setting up audit and logging accounts, and simplifying new account provisioning via Account Factory.

---

38. Q: How do you build a multi-tenant SaaS application on AWS?

A:

- Choose between **pooled** vs **isolated** tenant models.
- Use **Cognito** for tenant/user auth and separation.
- Leverage **Lambda, DynamoDB, and API Gateway** with tenant-based access.
- Use **resource tagging** and **IAM condition keys** for policy enforcement.

Scenario:

We designed a B2B SaaS app where each tenant had isolated DynamoDB tables. Cognito tokens contained tenant IDs, and API Gateway routed requests accordingly. Billing was done based on tagged usage.

---

39. Q: How would you integrate AWS with on-premise Active Directory?

A:

- Use **AWS Directory Service – AD Connector** for proxy integration.
- Use **VPN or Direct Connect** for network access.
- Integrate with **EC2, RDS, or FSx** for domain-joined resources.

Scenario:

A client needed Windows EC2s to join on-prem AD. We used AD Connector + Site-to-Site VPN. SSO was enabled for AWS Console using SAML federation via ADFS.

---

40. Q: How would you handle data archiving in AWS?

A:

- Use **S3 Glacier or Glacier Deep Archive** for long-term storage.
- Set **lifecycle rules** to transition data from S3 Standard → IA → Glacier.
- Use **Object Lock** for compliance retention.
- Index metadata with DynamoDB or Athena.

Scenario:

For a legal firm, we archived old case files in Glacier Deep Archive. Lifecycle rules transitioned S3 files after 90 days, saving 80% on storage cost. Retrieval was automated via S3 batch operations.

---

41. Q: How do you scale an ECS or Fargate service automatically?

A:

- Use **Application Auto Scaling** policies based on **CPU/memory** or custom **CloudWatch metrics**.
- Configure **target tracking** or **step scaling**.
- Use **Service Discovery** with Cloud Map for internal scaling.

Scenario:

Our API service on ECS Fargate auto-scaled from 2 to 12 tasks during peak traffic using a CPU threshold of 60%. We monitored scale-in events to avoid over-provisioning during idle periods.

---

42. Q: How do you manage blue/green deployment in RDS?

A:

- Use **RDS snapshot and restore** for staging.
- Use **read replicas** to promote to master during cutover.
- For Aurora: Use **blue/green deployments** (built-in) with zero-downtime switching.

Scenario:

During a major schema upgrade, we created an RDS blue environment using snapshots. Once validated, we used a DNS cutover. In Aurora, we used the new Blue/Green deployment feature to promote instantly.

---

43. Q: How do you architect a serverless data processing pipeline?

A:

- Use **S3 → Lambda → DynamoDB** for small scale.
- For streaming: **Kinesis Firehose** → **Lambda/Glue** → **S3**.
- Use **Step Functions** for orchestration.

Scenario:

IoT data from sensors was ingested via Kinesis. Firehose dumped raw data into S3. Glue ETL jobs transformed the data, then Athena queried it for reporting dashboards in QuickSight.

---

44. Q: How do you deal with noisy neighbors in a shared environment?

A:

- Use **resource limits** (CPU/memory) in ECS/Kubernetes.
- For Lambda, use **reserved concurrency** to isolate workloads.
- Separate tenants into **different accounts or VPCs**.
- Use **multi-tenant-aware design** for shared databases.

Scenario:

In a shared ECS cluster, one tenant's cron job hogged CPU. We applied task-level CPU limits and moved noisy workloads to a separate Fargate service to isolate impact.

---

45. Q: How would you set up a secure CI/CD pipeline in AWS?

A:

- Use **CodePipeline** with **CodeBuild/CodeDeploy** or integrate GitHub/GitLab.
- Store secrets in **Secrets Manager**, not in code.
- Apply **IAM least privilege** to pipeline roles.
- Use **artifact encryption** and **signing**.

Scenario:

Our pipeline used GitHub → CodeBuild → ECS deploy. IAM roles restricted builds to only access S3 and ECS. CodeBuild pulled DB credentials from Secrets Manager at runtime and rotated them every 15 days.

---

46. Q: How do you implement cross-account access securely in AWS?

A:

- Use **IAM Roles with AssumeRole** across accounts.
- Use **resource-based policies** (for S3, Lambda, KMS, etc.).
- Enable **CloudTrail** to audit cross-account activities.
- Restrict access using **external IDs** or conditions (aws:PrincipalOrgID).

Scenario:

We created a central logging account that other accounts assumed via a shared IAM role. Permissions were scoped tightly with conditions like SourceAccount and MFA enforced for human access.

---

47. Q: How do you manage custom domain names for APIs on AWS?

A:

- Use **API Gateway** custom domain mappings.
- Register/manage domain via **Route 53** or external DNS provider.
- Attach an **SSL certificate via ACM**, use **base path mappings**.
- Apply **WAF** and **throttling** for protection.

Scenario:

For a public REST API, we mapped api.myproduct.com to API Gateway using a wildcard ACM certificate. Route 53 handled DNS with health checks and failover.

---

48. Q: How do you enforce encryption on all AWS resources?

A:

- Enable **default encryption** on S3, EBS, RDS, and Lambda.
- Use **SCPs or Config Rules** to deny non-encrypted resource creation.
- Use **KMS CMKs** for custom key control.
- Audit with **AWS Config**, **Security Hub**, or **Macie**.

Scenario:

We enforced a company-wide Config rule: "EBS volumes must be encrypted." Any unencrypted volumes triggered a Lambda that notified the infra team via Slack and SNS.

---

49. Q: How do you implement role-based access control (RBAC) in AWS?

A:

- Define **IAM roles and policies** per job function.
- Group users via **IAM groups or federate via SSO/SAML**.
- Apply **resource-level permissions**, use **tags for access control**.
- Use **ABAC** (Attribute-Based Access Control) where needed.

Scenario:

DevOps engineers had an IAM group with full read/write on EC2, but no access to billing. Developers could deploy to ECS only in staging via role-based constraints using aws:TagKeys.

---

50. Q: How do you design for eventual consistency in AWS services like S3 or DynamoDB?

A:

- Assume **read-after-write latency** for overwrite PUTs in S3.
- In DynamoDB, handle eventual consistency with **retry logic** or **conditional writes**.
- Use **streams or versioning** to handle updates.

Scenario:

For an event-driven microservice with DynamoDB, we used conditional expressions to avoid overwrites and replayed changes from DynamoDB Streams to maintain sync with Elasticsearch.

---

51. Q: How do you support zero-downtime database migrations in AWS?

A:

- Use **AWS DMS (Database Migration Service)** for live replication.
- Enable **CDC (Change Data Capture)** for minimal downtime.

- Switch traffic with **Route 53** or **application reconfiguration**.
- Perform shadow testing before full cutover.

Scenario:

We migrated an on-prem Oracle DB to Aurora PostgreSQL using DMS. Cutover took <5 minutes with CDC syncing ongoing changes while the app was live.

---

52. Q: How do you protect sensitive data like PII in AWS?

A:

- Store encrypted at rest using **KMS**.
- Use **Macie** to detect sensitive data in S3.
- Apply **fine-grained IAM policies**.
- Mask or tokenize data during processing (e.g., via Glue, Lambda).

Scenario:

For GDPR compliance, we used Macie to flag unencrypted S3 objects containing names/emails. Glue ETL jobs tokenized PII before loading to Redshift for analytics.

---

53. Q: What's the best way to run periodic batch jobs in AWS?

A:

- Use **EventBridge (CloudWatch Events)** to trigger **Lambda**, **ECS**, or **Batch**.
- Use **Step Functions** for long-running or multi-step workflows.
- Monitor jobs with CloudWatch and add **retry logic**.

Scenario:

A nightly ETL job triggered via EventBridge invoked a Step Function that orchestrated S3 file movement, Glue data transformation, and Slack notifications.

---

54. Q: How do you handle application state in a serverless architecture?

A:

- Store state in **DynamoDB**, **S3**, or **Aurora Serverless**.
- Use **Step Functions** for long-running or stateful workflows.
- For idempotency, use **DynamoDB conditional writes** or **deduplication IDs**.

Scenario:

Our serverless order processing app used DynamoDB for order state and Step Functions to handle retries, timeouts, and failed transactions. We used OrderID as the unique key for idempotent writes.

---

55. Q: How do you support multi-region disaster recovery for APIs?

A:

- Deploy resources in multiple regions with **infrastructure as code**.
- Use **Route 53 failover routing** for DNS-based DR.
- Replicate data via **Aurora Global DB**, **S3 CRR**, or **DynamoDB Global Tables**.
- Run **periodic failover simulations**.

Scenario:

A B2C app had active-passive failover across us-east-1 and eu-west-1. S3 and DynamoDB were globally replicated, and Route 53 health checks routed traffic to the passive region during failover drills.

---

56. Q: How do you design a secure data ingestion pipeline into AWS?

A:

- Ingest via **API Gateway**, **Kinesis**, or **S3** with pre-signed URLs.
- Use **VPC endpoints** or **PrivateLink** to avoid data exposure on the internet.
- Encrypt in transit with **HTTPS/TLS**, at rest with **KMS**.
- Authenticate using **IAM roles**, **Cognito**, or **custom authorizers**.

Scenario:

A customer-facing IoT platform ingested telemetry data via Kinesis Firehose behind a PrivateLink. Devices used signed URLs and JWT tokens for secure, per-device access. Data landed in S3, encrypted with KMS.

---

57. Q: How do you implement centralized secrets management across multiple AWS accounts?

A:

- Use **AWS Secrets Manager** in a central account.
- Use **resource policies** to allow access from specific IAM roles in other accounts.
- Apply **KMS key policies** to control decryption access.
- Automate with **cross-account IAM roles** and **resource sharing via AWS RAM**.

Scenario:

We centralized database credentials in Secrets Manager in the shared "security" account. Application roles from dev/stage/prod accounts accessed secrets via resource policies and cross-account IAM roles.

---

58. Q: How would you architect a mobile backend on AWS?

A:

- Use **API Gateway + Lambda** for backend logic.
- Use **Cognito** for authentication and user pools.
- Store data in **DynamoDB** and assets in **S3**.
- Push updates via **SNS** or **AppSync (GraphQL)** for real-time use.

Scenario:

We built a social media app backend using API Gateway + Lambda + DynamoDB. Cognito managed users and Facebook login. S3 stored user uploads. CloudWatch tracked API latency.

---

59. Q: How do you scale Lambda functions? What are the limits?

A:

- Lambda scales automatically with requests.
- By default, you get **1,000 concurrent executions** per region (can be increased).
- Use **reserved concurrency** to isolate functions.
- Use **provisioned concurrency** for low-latency use cases.

Scenario:

During a flash sale, one Lambda exceeded concurrency limits, affecting other workflows. We isolated it using reserved concurrency and used provisioned concurrency for critical checkout functions.

---

60. Q: How do you enforce multi-factor authentication (MFA) in AWS for users and roles?

A:

- Require MFA for users via **IAM policies** using aws:MultiFactorAuthPresent.
- Use **SAML 2.0 federation with MFA** at the identity provider level.
- Require **session tags** or external IDs for role assumptions.

Scenario:

All developers accessed the AWS console through SSO (Okta) with enforced MFA. For CLI access, policies denied actions unless MFA was used and session duration was limited to 1 hour.

---

61. Q: How do you implement real-time analytics in AWS?

A:

- Ingest via **Kinesis Data Streams** or **Firehose**.
- Use **Lambda** or **Kinesis Analytics** to process data.
- Store results in **S3**, **DynamoDB**, or **Redshift**.
- Visualize via **QuickSight** or third-party BI tools.

Scenario:

We built a real-time dashboard for a food delivery app using Kinesis Streams → Lambda → DynamoDB. The UI pulled data every 5 seconds via WebSocket to show live order statuses.

---

62. Q: How do you implement fine-grained access control to S3 buckets?

A:

- Use **S3 bucket policies** with conditions (e.g., aws:username, aws:PrincipalOrgID).
- Enable **IAM policy conditions** using tags or prefixes.
- Use **S3 Access Points** for scoped access.
- Use **S3 Object ACLs** sparingly, if needed.

Scenario:

Each customer uploaded documents to S3 using a specific prefix (/customer_id/). IAM roles were restricted to their own prefix using a condition: "s3:prefix": ["customer123/*"].

---

63. Q: How do you design a CI/CD pipeline for a containerized app in AWS?

A:

- Use **CodePipeline** with **CodeBuild**, **ECR**, and **ECS** or **EKS**.
- Use **CodeDeploy** or GitHub Actions for deployment.
- Store secrets in **Secrets Manager**, not in code.
- Include stages for **build, test, deploy, and approval**.

Scenario:

For a Node.js app, the CI/CD pipeline ran in GitHub Actions, built Docker images, pushed to ECR, and triggered an ECS deployment using CodeDeploy with blue/green strategy. Slack alerts were sent after deployment.

---

64. Q: How do you deal with cold starts in Lambda?

A:

- Use **provisioned concurrency** to keep Lambda warm.

- Keep function size small and avoid heavy SDK imports.
- Avoid VPC attachment unless necessary — or use **VPC endpoints** and **ENI reuse**.

Scenario:

A financial app had latency issues on first call. We enabled provisioned concurrency (min 2 instances) for low-latency endpoints, reducing 99th percentile response time by 60%.

---

65. Q: How do you handle schema evolution in AWS data lakes?

A:

- Use **Glue Schema Registry** or **versioning** in metadata.
- Prefer formats like **Parquet**, **Avro** for flexibility.
- Use **Athena/Glue Catalog** with version control on partitions.
- Implement **ETL pipelines** to adapt older formats.

Scenario:

When the user_profile schema changed (new fields), Glue jobs transformed old records to new format using schema mapping. Athena read both formats using updated partitions.

---

66. Q: How do you optimize Lambda performance for heavy workloads?

A:

- Break into smaller, **event-driven microfunctions**.
- Use **async invocation** with **DLQs** for retries.
- Choose higher **memory allocations** for better CPU.
- Use **provisioned concurrency** for predictable latency.
- Optimize **init code** to reduce cold starts.

Scenario:

We optimized a PDF-generation Lambda by increasing memory from 512MB to 2GB, reducing execution time by 40%. Cold starts were eliminated with provisioned concurrency on high-traffic routes.

---

67. Q: How do you architect an application with high availability across AWS regions?

A:

- Deploy to **multiple regions** (active-active or active-passive).
- Use **Route 53** with **failover routing** or **latency-based routing**.
- Replicate data using **S3 CRR**, **Aurora Global DB**, or **DynamoDB Global Tables**.
- Automate infrastructure using **CloudFormation StackSets** or **Terraform**.

Scenario:

For a customer portal, we used latency-based routing between us-east-1 and eu-central-1. Data was synchronized via Aurora Global DB and DNS failover was tested monthly.

---

68. Q: How do you monitor security in real-time on AWS?

A:

- Use **GuardDuty** for intelligent threat detection.
- Set up **CloudTrail** and **Config** for audit/compliance.
- Aggregate findings with **Security Hub**.
- Enable **Macie** for S3 data privacy monitoring.
- Create alerts via **EventBridge → SNS → Slack/Email**.

Scenario:

When GuardDuty detected unauthorized port scanning on a bastion, it triggered an EventBridge rule that revoked the security group rule and notified SecOps via Slack.

---

69. Q: How do you manage long-running background jobs in AWS?

A:

- Use **Step Functions** with Lambda or ECS tasks.
- Use **SQS** for decoupling and job buffering.
- For large-scale compute, use **AWS Batch**.
- Use **DynamoDB TTL** or **CloudWatch Events** for job expiration.

Scenario:

A genomic processing app used Step Functions to manage 10+ stages over 2–3 hours. Each job was run in Fargate containers triggered by state machine transitions, with error handling and retry.

---

70. Q: How do you restrict data access within a shared DynamoDB table (multi-tenant)?

A:

- Use a **partition key per tenant** (e.g., tenant_id).
- Use **IAM policies with condition keys** (e.g., dynamodb:LeadingKeys).
- Apply **fine-grained access control** using tokens from Cognito.

Scenario:

In a multi-tenant SaaS, all data lived in one DynamoDB table. IAM roles used LeadingKeys to restrict access to rows only under the user's tenant_id.

---

71. Q: How do you implement observability in a distributed microservices system on AWS?

A:

- Use **X-Ray** for distributed tracing.
- **CloudWatch Logs & Metrics** for service-level logging/alerts.
- Export logs to **OpenSearch** or **Datadog** for visualization.
- Add **correlation IDs** for request tracking.

Scenario:

In a Lambda/ECS hybrid system, we added correlation IDs to each request via API Gateway. X-Ray helped us trace latency spikes in a downstream Lambda used for DB inserts.

---

72. Q: How do you secure communication between microservices in AWS?

A:

- Use **mutual TLS (mTLS)** in service mesh (e.g., **App Mesh**, **Istio on EKS**).
- Use **private DNS** and **service discovery**.
- Secure endpoints via **IAM roles**, **security groups**, or **NACLs**.
- Log and monitor with **VPC Flow Logs**.

Scenario:

In EKS, we deployed Istio with mTLS enabled by default. Each microservice had its own namespace and NetworkPolicy. Communication outside the cluster required IAM authentication.

---

73. Q: How do you back up and restore infrastructure in AWS?

A:

- Use **CloudFormation/Terraform** for infrastructure as code (version controlled).
- Take **EBS snapshots**, **RDS snapshots**, **S3 versioning**.
- Use **AWS Backup** for centralized backup policies and audit.
- Store snapshots across **multiple regions** for redundancy.

Scenario:

A daily AWS Backup policy took EBS and RDS snapshots at 2 AM. When an app update caused data corruption, we rolled back to the previous night's RDS snapshot with minimal impact.

---

74. Q: How do you implement rate limiting for public APIs in AWS?

A:

- Use **API Gateway throttling** (per method/usage plan).
- Apply **WAF rules** for IP-based rate limits.
- Use **Lambda authorizers** to enforce quotas per user.
- Log access and deny excessive patterns.

Scenario:

A marketing API exposed to partners used usage plans and API keys. Each partner had their own limit (100 RPS). Excess traffic was throttled and logged to CloudWatch for auditing.

---

75. Q: How do you maintain service availability during AWS region outages?

A:

- Design for **multi-region** redundancy.
- Use **Route 53 health checks** with **failover routing**.
- Keep **read replicas** or **Global Tables** ready.
- Ensure **CI/CD pipelines** can deploy to any region.

Scenario:

During the us-east-1 outage, our app failed over to us-west-2. S3 content was pre-synced via CRR. Route 53 automatically routed users to the backup region, keeping the platform online.

---

76. Q: How do you automate patch management for EC2 instances?

A:

- Use **AWS Systems Manager Patch Manager** to schedule patch baselines.
- Group EC2s using **tags** or **resource groups**.
- Use **Maintenance Windows** for controlled patching.
- Monitor compliance with **SSM Compliance Reports**.

Scenario:

We scheduled patching every Sunday at 2 AM for Linux servers in production. EC2s were tagged by environment, and a Maintenance Window targeted these tags. Compliance reports were sent to the InfoSec team weekly.

---

77. Q: How do you secure cross-region replication between S3 buckets?

A:

- Enable **S3 Cross-Region Replication (CRR)**.
- Encrypt data using **KMS** keys in both source and destination.
- Add **bucket policies** to restrict access.
- Enable **versioning** and **Object Lock** if required.

Scenario:

For a content delivery pipeline, CRR was enabled between buckets in us-west-2 and ap-south-1. Both buckets used KMS encryption, and access was restricted using bucket and VPC endpoint policies.

---

78. Q: How do you handle operational visibility for EKS clusters?

A:

- Enable **Container Insights** for EKS via CloudWatch.
- Use **Prometheus + Grafana** with **AMP** (Amazon Managed Prometheus).
- Enable **audit logging**, **VPC Flow Logs**, and **Kubernetes RBAC logs**.
- Use **Fluent Bit/Fluentd** to ship logs to OpenSearch or S3.

Scenario:

For a media analytics platform on EKS, we used Prometheus to monitor pod resource usage, Grafana for dashboards, and Fluent Bit to send logs from all pods to OpenSearch for indexing.

---

79. Q: How do you implement audit and compliance controls across multiple AWS accounts?

A:

- Use **AWS Organizations** with **Service Control Policies (SCPs)**.
- Centralize logs using **CloudTrail Organization Trails**.
- Enable **AWS Config**, **Security Hub**, and **GuardDuty** across all accounts.
- Automate remediation using **SSM Automation** or **Lambda**.

Scenario:

A finance company had 12 AWS accounts. We enabled Org-wide CloudTrail and AWS Config rules to track S3 public access and IAM changes. Violations triggered auto-remediation and Slack notifications.

---

80. Q: How do you reduce container image vulnerabilities in ECS/EKS?

A:

- Use **Amazon ECR image scanning** or **third-party tools** (e.g., Trivy, Clair).
- Enforce **least privilege Dockerfiles** (no root user).
- Sign images using **ECR image signing (SigV4)**.
- Automate scanning in CI/CD pipeline.

Scenario:

CI pipeline scanned Docker images using Trivy before pushing to ECR. Critical CVEs blocked the deployment. We enforced base image updates monthly via GitHub Dependabot.

---

81. Q: How do you isolate environments (e.g., dev, stage, prod) in AWS?

A:

- Use **separate AWS accounts** for each environment.
- Apply **SCPs** to restrict permissions.
- Tag resources for **cost allocation** and **access control**.
- Use separate **VPCs**, **KMS keys**, and **IAM roles** per environment.

Scenario:

Dev/stage/prod environments were hosted in different AWS accounts under AWS Organizations. IAM roles were scoped per account, and S3 buckets had environment-specific KMS keys and policies.

---

82. Q: How do you handle large file uploads (>5 GB) to S3?

A:

- Use **S3 multipart upload** (required for files >5 GB, recommended >100 MB).
- Use **presigned URLs** for client-side uploads.
- Monitor upload status via **EventBridge or Lambda**.

Scenario:

A video editing platform allowed users to upload 20 GB files via presigned URLs. The frontend used multipart upload with progress tracking. Lambda functions processed metadata once upload events hit S3.

---

83. Q: How do you enable canary testing in AWS Lambda?

A:

- Deploy using **Lambda aliases** (e.g., prod, canary).
- Use **weighted traffic shifting** with **CodeDeploy**.
- Monitor metrics like **error rate** or **latency** via CloudWatch.
- Roll back automatically on failure.

Scenario:

A critical pricing function used canary deploys where 10% of traffic hit the new version. If errors exceeded 2% within 5 minutes, CodeDeploy rolled back to the stable version automatically.

---

84. Q: How do you support bring-your-own-IP (BYOIP) in AWS?

A:

- Use **BYOIP** with **Amazon Global Accelerator** or **EC2**.
- Announce IPs via **ROA (Route Origin Authorization)**.
- Manage using **AWS CLI or console** under EC2 > BYOIP.
- Useful for **IP whitelisting** with partners.

Scenario:

A telecom provider migrated to AWS but needed to retain its static IPs for regulatory reasons. We used BYOIP with Global Accelerator and routed traffic to EC2 behind an NLB for consistent client IP visibility.

---

85. Q: How do you handle stateful applications in Kubernetes (EKS)?

A:

- Use **StatefulSets** for pods with stable IDs and volumes.
- Use **EBS** or **EFS** for persistent storage.
- Define **PersistentVolumeClaims (PVCs)** and manage lifecycle.
- Backup volumes using **AWS Backup** or **Velero**.

Scenario:

A PostgreSQL instance was deployed on EKS using a StatefulSet. EBS volumes were attached to each pod via PVCs. We used Velero for nightly backups and restored in another namespace for DR testing.

---

86. Q: How do you enforce tagging policies across an organization in AWS?

A:

- Use **AWS Organizations Tag Policies** to define required tags.
- Enforce tagging at creation via **SCPs** or **IAM condition keys**.
- Use **AWS Config Rules** to audit non-compliant resources.
- Automate remediation using **Lambda or SSM**.

Scenario:

We applied a tag policy requiring Environment, Owner, and CostCenter on all EC2 and S3 resources. A Config Rule identified non-compliant resources and triggered an SSM doc to add missing tags.

---

87. Q: How do you manage IP whitelisting for APIs in AWS?

A:

- Use **API Gateway resource policies** to restrict by IP.
- Use **WAF IP sets** for allow/deny lists.
- Apply **NACLs/Security Groups** at the VPC level for EC2/ECS APIs.

Scenario:

For a private B2B API, we restricted access to partner IPs via a WAF IP set. API Gateway blocked all traffic except the whitelisted CIDRs, and usage was logged to CloudWatch.

---

88. Q: How do you implement zero-trust architecture in AWS?

A:

- Use **identity-based access control** via IAM.
- Require **MFA**, **device posture checks**, and **short-lived tokens**.
- Use **PrivateLink** and **VPC Endpoints** instead of public internet.
- Monitor with **GuardDuty** and **CloudTrail**.

Scenario:

An internal admin portal was exposed only via PrivateLink. Developers assumed IAM roles with session durations of 1 hour and required device-based authentication via SSO.

---

89. Q: How do you use AWS CDK for infrastructure automation?

A:

- CDK (Cloud Development Kit) allows **code-based IaC** in TypeScript, Python, Java, etc.
- Synthesizes into **CloudFormation templates**.
- Supports **construct reuse** and **multi-stack deployments**.

Scenario:

We built an internal library of CDK constructs (VPC, ECS, S3) for dev teams. Pipelines auto-synthesized the stacks into CloudFormation and deployed via CodePipeline.

---

90. Q: How do you reduce latency in global applications on AWS?

A:

- Use **Amazon CloudFront** for edge caching.
- Use **Global Accelerator** for TCP/UDP routing.
- Deploy app across regions using **Route 53 latency routing**.
- Optimize data using **gzip/compression** and **content minification**.

Scenario:

For a SaaS dashboard, CloudFront cached JS bundles, reducing TTFB by 65%. Global Accelerator routed API traffic to the closest region, improving user experience worldwide.

---

91. Q: How do you implement a custom authentication flow in Cognito?

A:

- Use **Cognito Triggers** (PreSignUp, PostConfirmation, etc.).
- Integrate with **Lambda functions** for custom logic (e.g., OTP, captcha).
- Use **identity pools** for federated identities.

Scenario:

For a fintech onboarding app, we added a PreSignUp Lambda trigger that validated user emails against a whitelist and sent custom OTPs via SES before account confirmation.

---

92. Q: How do you manage multi-cloud or hybrid deployments with AWS?

A:

- Use **Transit Gateway**, **Direct Connect**, or **VPN** to connect to on-prem/cloud.
- Deploy using **Terraform** or **multi-cloud tools** like **HashiCorp Boundary**, **Vault**, or **Kubernetes**.
- Use **CloudEndure** or **MGN** for migration.

Scenario:

A client had workloads in Azure and AWS. We connected both via VPN, synchronized data to S3 from Azure Blob, and deployed a centralized monitoring plane using Datadog.

---

93. Q: How do you monitor resource limits in AWS to avoid service disruptions?

A:

- Use **Service Quotas** dashboard and **CloudWatch Alarms** on usage metrics.

- Set up **budgets and alerts**.
- Track API throttling via **CloudTrail** or **X-Ray**.

Scenario:

We hit a Lambda concurrency limit during an event. After that, we set up CloudWatch metrics for concurrency and invoked an SNS alert when usage crossed 80% of quota.

---

94. Q: How do you secure CI/CD pipelines in AWS?

A:

- Use **IAM roles with least privilege** for CodeBuild/CodeDeploy.
- Store secrets in **Secrets Manager** or **Parameter Store**, not hardcoded.
- Scan code using **CodeGuru Reviewer** or **SonarQube**.
- Validate IaC templates for compliance using **CFN-Nag** or **Checkov**.

Scenario:

A CodePipeline for ECS used IAM roles scoped only to ECR, ECS, and S3. Secrets were pulled securely from SSM. All builds were scanned using Trivy and blocked on high-severity CVEs.

---

95. Q: How do you handle cost allocation and chargeback in AWS?

A:

- Use **resource tags** (e.g., Project, Team, Environment) for allocation.
- Enable **Cost Explorer** and **Budgets**.
- Export **Cost & Usage Reports (CUR)** to S3 and query with Athena.

Scenario:

Each department had a CostCenter tag. A daily Athena job parsed CUR data into a report sent to finance and team leads. This drove accountability and budget forecasting.

---

96. Q: How do you manage temporary access in AWS securely?

A:

- Use **IAM roles with session duration limits**.
- Use **STS AssumeRole** for cross-account or temporary access.
- Use **IAM Access Analyzer** to detect unintended access.

Scenario:

Contractors were granted time-bound access using AssumeRole with 1-hour sessions. A Lambda auto-disabled the role after the project end date and removed any associated policies.

---

97. Q: How do you implement blue/green infrastructure deployment with Terraform?

A:

- Deploy two sets of infrastructure (v1, v2) using modules.
- Route traffic via **Route 53**, **ALB target groups**, or **API Gateway stage**.
- Use **Terraform workspaces** or duplicate modules.
- Switch over once testing is complete.

Scenario:

We deployed both v1 and v2 ECS services using Terraform modules. ALB target groups pointed to v2 after validation, and v1 was decommissioned in the same plan.

---

98. Q: How do you manage event-driven retries and DLQs in serverless architectures?

A:

- Use **Lambda Destinations** for async invocations.
- Configure **maximum retry attempts** and **DLQs** (e.g., SQS, SNS).
- Monitor failures with **CloudWatch Logs** and **metrics filters**.

Scenario:

A Lambda processing S3 uploads had 2 retries configured. If it failed, the payload was sent to an SQS DLQ. A CloudWatch Alarm triggered a remediation Lambda to reprocess the files.

---

99. Q: How do you support real-time notification systems in AWS?

A:

- Use **SNS** for pub/sub notifications (SMS, email, HTTP).
- Use **WebSocket API in API Gateway** for real-time app updates.
- Use **EventBridge** for routing events across services.

Scenario:

An e-commerce app used EventBridge to capture order events. SNS notified users via SMS and email. WebSocket APIs pushed status updates to the frontend as the order progressed.

---

100. Q: How do you prepare for a Well-Architected Review in AWS?

A:

- Review the **5 pillars**: Operational Excellence, Security, Reliability, Performance Efficiency, and Cost Optimization.
- Use the **Well-Architected Tool** in the console.
- Remediate **high-risk issues** (HRIs).
- Document all design decisions.

Scenario:

We used the Well-Architected Tool before a quarterly audit. Findings showed overly permissive IAM roles and lack of monitoring. We implemented IAM least privilege, centralized logging, and cost tagging before the next review.

101. Q: How do you implement a multi-tier architecture in AWS?

A:

- Use **VPC** with public and private subnets.
- Place **ALB** in the public subnet.
- App layer (EC2, ECS, Lambda) in private subnets.
- DB layer (RDS, Aurora) in private subnets with no internet access.
- Use **NAT Gateway** for outbound internet access from private subnets.

Scenario:

For a client's e-commerce platform, we built a 3-tier architecture using ALB + EC2 in an Auto Scaling Group (app tier) + RDS for MySQL in a private subnet. NAT Gateway allowed updates while keeping DB secure.

---

102. Q: How would you design a disaster recovery (DR) solution in AWS?

A:

- Use strategies like **Backup & Restore**, **Pilot Light**, **Warm Standby**, or **Multi-Site Active-Active**.
- Replicate data using **Cross-Region S3**, **RDS Read Replica**, or **DynamoDB Global Tables**.
- Use **Route 53 health checks** to redirect traffic.

Scenario:

For a fintech firm, we used warm standby with cross-region RDS replication and S3 sync. Route 53 handled DNS failover, and CloudFormation templates allowed rapid provisioning in the DR region.

---

103. Q: What are some ways to secure S3 buckets?

A:

- Use **Bucket Policies** to control access.
- **Block Public Access** settings.
- Enable **S3 Server-Side Encryption (SSE-S3, SSE-KMS)**.
- Enable **MFA Delete**.
- Use **Access Analyzer** and **CloudTrail**.

Scenario:

We once found a dev S3 bucket publicly accessible. We used Access Analyzer to audit all buckets, applied policies to block public access, and moved to SSE-KMS for sensitive client data.

---

104. Q: How would you migrate an on-premise database to AWS?

A:

- Use **AWS DMS (Database Migration Service)** for online/live migrations.
- Use **Snowball** for large data volume.
- For homogeneous migration (Oracle to Oracle), use native tools with DMS.
- Validate using **Schema Conversion Tool (SCT)**.

Scenario:

We migrated a 1TB Oracle database to RDS Oracle using DMS with minimal downtime. SCT helped with schema compatibility, and we tested cutover in a staging environment before go-live.

---

105. Q: How do you manage secrets and sensitive data in AWS?

A:

- Use **AWS Secrets Manager** or **SSM Parameter Store** (SecureString).
- Set automatic rotation using **Lambda triggers**.
- Restrict access using **IAM policies**.
- Use **KMS** to encrypt secrets.

Scenario:

In a CI/CD pipeline, we stored DB credentials in Secrets Manager with IAM-restricted access for ECS tasks. We enabled automatic rotation and audit logs via CloudTrail.

---

106. Q: What's your approach for setting up CI/CD pipelines in AWS?

A:

- Use **CodeCommit**, **CodeBuild**, **CodeDeploy**, and **CodePipeline**.
- Integrate with **GitHub/GitLab** for source.
- Use **CloudFormation or Terraform** for infrastructure deployment.
- Add **manual approval** stages and deploy to different environments.

Scenario:

For a microservices project, we used CodePipeline with GitHub -> CodeBuild (Docker) -> ECS deploy via CodeDeploy. We included approvals for staging and used SSM to inject environment secrets securely.

---

107. Q: How do you design a VPC for a production environment?

A:

- Create VPC with **public and private subnets** across multiple AZs.
- Use **NAT Gateway** for private subnets.
- **Internet Gateway** for public subnets.
- Enable **VPC Flow Logs**, use **NACLs and Security Groups**.
- Use **VPC Endpoints** for S3/DynamoDB.

Scenario:

We split workloads into subnets: ALB in public, ECS and RDS in private. NAT allowed patching. VPC Endpoints reduced latency for S3 access. Flow Logs helped detect abnormal access patterns.

---

108. Q: How would you handle compliance and auditing in AWS?

A:

- Use **AWS Config** to track resource compliance.
- Use **CloudTrail** for API activity.
- **AWS Organizations + SCPs** for governance.
- Enable **GuardDuty**, **Security Hub**, and **Access Analyzer**.

Scenario:

During a PCI-DSS audit, we used AWS Config to show encryption compliance, and CloudTrail to trace access logs. Security Hub helped consolidate findings across 10 accounts in the org.

---

109. Q: How do you monitor and troubleshoot AWS infrastructure?

A:

- Use **CloudWatch** for metrics, logs, dashboards, and alarms.
- Use **X-Ray** for distributed tracing.

- **VPC Flow Logs**, **ELB access logs**, and **RDS Enhanced Monitoring**.
- Integrate with third-party tools (e.g., Datadog, Prometheus).

Scenario:

A sudden spike in latency was traced using CloudWatch dashboards and X-Ray traces, which revealed a slow DB query. We tuned the query and added read replicas to scale.

---

110. Q: What's your strategy for designing a serverless application in AWS?

A:

- Use **API Gateway + Lambda + DynamoDB/S3**.
- Leverage **EventBridge** for event-driven architecture.
- Secure with **IAM roles**, **Cognito**, **WAF**, and **throttling**.
- Monitor via **CloudWatch Logs**, **X-Ray**.

Scenario:

For an IoT telemetry system, we built a fully serverless pipeline: IoT Core → Lambda → DynamoDB. We used EventBridge to trigger anomaly alerts and CloudWatch for usage analytics.
